Análisis Factorial

Maisy Samai Vázquez Sánchez

2022-05-21

Análisis Factorial

Introducción

El análisis factorial sirve para explicar un conjunto de variables observadas a través de un grupo de variables no observadas.Ayuda a la reducción de dimensionalidad. Se utiliza en la reducción de los datos para identificar un pequeño número de factores que explique la varianza observada en un número mayor de variables manifestadas.

Matriz de trabajo

1.- Se trabajó con la matriz **statex77** , extraída del paquete *datos* que se encuentra precargado en R, es una matriz de datos cuantitativos y contiene información de los de EU.

```
x<-as.data.frame(state.x77)
```

2.- Quitar los espacios de los nombres de las variables de las columnas 4 y 6 para no tener problemas.

```
colnames(x)[4]="Life.Exp"
colnames(x)[6]= "HS.Grad"
```

3.- Separa n (estados) y p (variables), para en una tener el número de individuos y en la otra el número de variables.

```
n<-dim(x)[1]
p<-dim(x)[2]
```

La matriz cuenta con 50 observaciones y 8 variables. Como se mencionó, la matriz de datos es cuantitativa.

3.- Nombre de las variables.

```
colnames(x)
```

```
## [1] "Population" "Income"     "Illiteracy" "Life.Exp"   "Murder"
## [6] "HS.Grad"    "Frost"      "Area"
```

4.- Se buscan datos perdidos en la matriz.

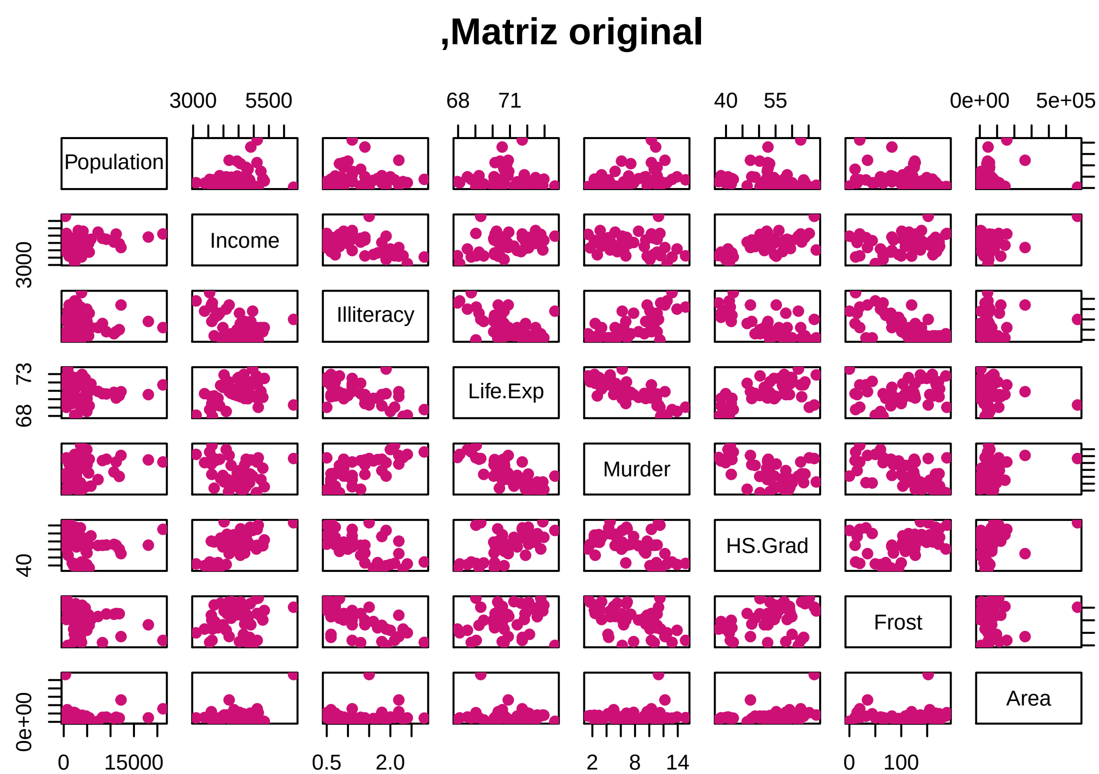
```r
anyNA(x)
```

```
## [1] FALSE
```

No se encuentran valores nulos en la matriz.

4.- Generación de un **scater plot** para la visualización de variables originales.

```r
pairs(x, col="#CD1076", pch=19, main=",Matriz original")
```



Se puede observar como la mayoria de las variables tienen una relación muy baja e incluso negativa.

Transformación de alguna variables.

1.- Aplicamos logaritmo para las columnas 1,3 y 8

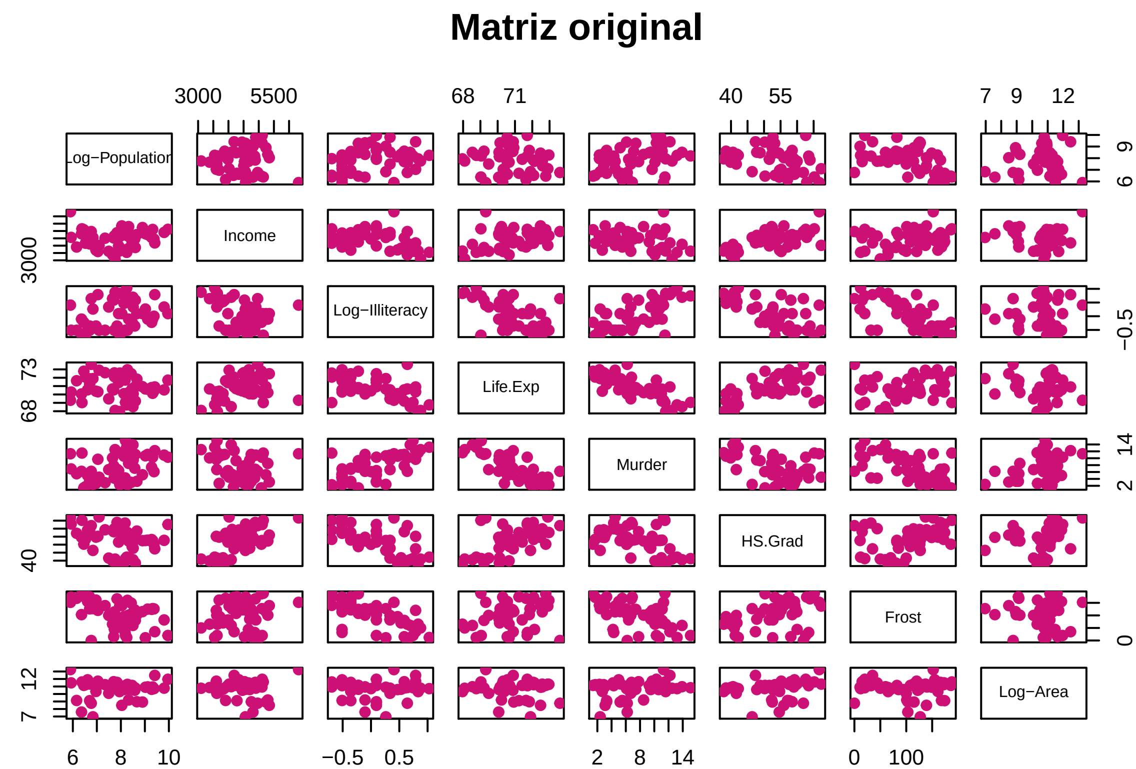
```r
x[,1]<-log(x[,1])
colnames(x)[1]<-"Log-Population"

x[,3]<-log(x[,3])
colnames(x)[3]<-"Log-Illiteracy"

x[,8]<-log(x[,8])
colnames(x)[8]<-"Log-Area"
```

2.-Gráfico scater para la visualización de la matriz original con 3 variables que se incluyeron.

```
pairs(x,col="#CD1076", pch=19, main="Matriz original")
```



Nota: Como las variables tiene diferentes unidades de medida, se implementa la matriz de correlaciones para estimar la matriz de carga.

Reducción de la dimensionalidad.

Análsis Factorial de componentes principales (PCFA).

1.- Calcular la matriz de medias y de correlaciones. ## Matriz de medias

```
mu<-colMeans(x)
mu
```

```
## Log-Population          Income Log-Illiteracy        Life.Exp          Murder
##    7.863443e+00    4.435800e+03    3.128251e-02    7.087860e+01    7.378000e+00
##         HS.Grad           Frost        Log-Area
##    5.310800e+01    1.044600e+02    1.066237e+01
```

Matriz de correlaciones.

```r
R<-cor(x)
R
```

```

## [8] 1.0000000
```

Estimacion de la matriz de carga

Nota: Se estima la matriz de carga usando los autovalores y autovectores. Se aplica la rotación *varimax*.

Se hace la primera estimación de Lamda mayúscula y se calcula multiplicando la matriz de los 3 primeros autovectores por la matriz diagonal formada por la raíz cuadrada de los primeros 3 autovalores.

```
L.est.1<-eigen.vec[,1:3] %*% diag(sqrt(eigen.val[1:3]))
L.est.1
```

```
